GLOSSARY

catchment area.--An area surrounded by a continuous ridge within which all runoff is expected to join into a single flow stream, and which extends to the point of junction of this flow stream (downstream) with the ridge. Natural boundaries, manmade boundaries, or minimum size of pipe are criteria which can be used to define the catchment (Alley, 1976).

constituent load.--The total amount of a selected constituent in a storm runoff, or a specified period of time, discharged into a receiving water.

impervious areas.--Areas which do not permit percolation of water, such as streets, sidewalks, roofs, and paved parking lots.

impervious areas, effective.--Impervious areas which are connected and, in turn, connect to some means of conveying the runoff out of the areas, such as roofs which drain onto driveways, streets, sidewalks, and paved parking lots.

impervious areas, noneffective.--Impervious areas which are not connected to other impervious areas and which drain to pervious areas, such as roofs which drain onto lawns.

land use.--A term which relates to both the physical characteristics of the land surface and the human activities associated with the land surface (Alley, 1976).

model calibration.--The process of fitting a model to a set of observed data. This is done by changing unknown or uncertain model parameters systematically within their allowable ranges until a "best" fit of the model to the observed data is achieved (Alley, 1976).

pervious areas.--Areas that allow percolation of water, such as lawns and fields of porous material.

receiving water.--"Natural" body of water that runoff from one or more catchments enters; this includes a tributary, river, estuary, bay, lake, or other body of water.

HYDROLOGIC DATA FOR URBAN STORM RUNOFF FROM THREE LOCALITIES
IN THE DENVER METROPOLITAN AREA, COLORADO

By Sherman R. Ellis

ABSTRACT

Urban storm-runoff data, collected from 1975 to 1977, on three catchment areas in the Denver metropolitan area are presented in this report. The catchments are predominantly a single-family residential catchment area in Littleton, a multifamily residential and commercial catchment area in Lakewood, and a high-density residential and commercial catchment area in Denver. Precipitation, rainfall-runoff, snowmelt-runoff, water-quality (common constituents, nutrients, biochemical oxygen demand, coliform bacteria, and solids, trace elements, and pesticides), and catchment-area data are necessary to use the U.S. Environmental Protection Agency's Storm Water Management Model III. The urban storm-runoff data may be used by planning, water-management, and environmental-protection agencies to assess the impact of urban storm runoff on the hydrologic system.

INTRODUCTION

Colorado and, in particular, the Denver metropolitan area are experiencing an increase in population and industry that is having a profound effect on water quality and on the usefulness of streams draining the area. Water-quality problems can be unusually severe in urban areas as a result of dense population and numerous industrial operations. The quality of the urban storm runoff flowing into the receiving waters is a factor that needs to be considered in waste-treatment-management systems because of the potential for pollution by the runoff.

Public Law 92-500, the Federal Water Pollution Control Act, (amendment of 1972) Section 208, requires the development and implementation of a plan for a coordinated waste-treatment-management system. State, county, and local agencies have directed attention to the identification of major sources of water pollution--untreated or inadequately treated domestic and industrial waste. Ultimately, though, attention needs to be directed toward identification and description of less obvious water-pollution sources. Storm-water runoff is one such source of water-quality degradation. A hydrologic-data base is necessary to permit determination of the magnitude and type of pollution caused by storm-water runoff.

During 1975, the U.S. Geological Survey entered into separate, but coordinated, cooperative agreements with the Denver Board of Water Commissioners, the Denver Regional Council of Governments, and the Urban Drainage and Flood Control District to investigate the quantity and quality of urban storm runoff originating from three catchment areas in the Denver metropolitan area. The catchment areas selected were a single-family residential catchment area in Littleton where storm runoff flows out of the catchment area in a tributary to Big Dry Creek, a multifamily residential and commercial catchment area in Lakewood where storm runoff flows out of the catchment area through a storm drain at North Avenue on the Denver Federal Center, and a high-density residential and commercial catchment area in Denver where storm runoff flows out of the catchment area through a storm sewer at Thirty-sixth Street. Monitoring sites were established by the U.S. Geological Survey at the points where the storm runoff leaves each catchment area. The identification of the monitoring sites used in this report are: 06710200 Big Dry Creek tributary at Littleton; 06711635 North Avenue Storm Drain at Denver Federal Center, at Lakewood; and 06714100 Thirty-sixth Street Storm Sewer at Denver. The locations of the monitoring sites are shown on figure 1 and general information about the sites is summarized in table 1.

Table 1.--Selected data for monitoring sites
and their catchment areas

U.S. Geological Survey downstream order number	Name of monitoring site	Latitude- longitude of monitoring site	Drainage area, in acres	Percentage of area covered by effective impervious surfaces
06710200	Big Dry Creek tributary at Littleton-----	39°35'46", 104°57'06"	606	15
06711635	North Avenue Storm Drain at Denver Federal Cen- ter, at Lakewood-----	39°43'21", 105°07'47"	76.7	30
06714100	Thirty-sixth Street Storm Sewer at Denver-	39°46'23", 104°58'46"	2,246	40

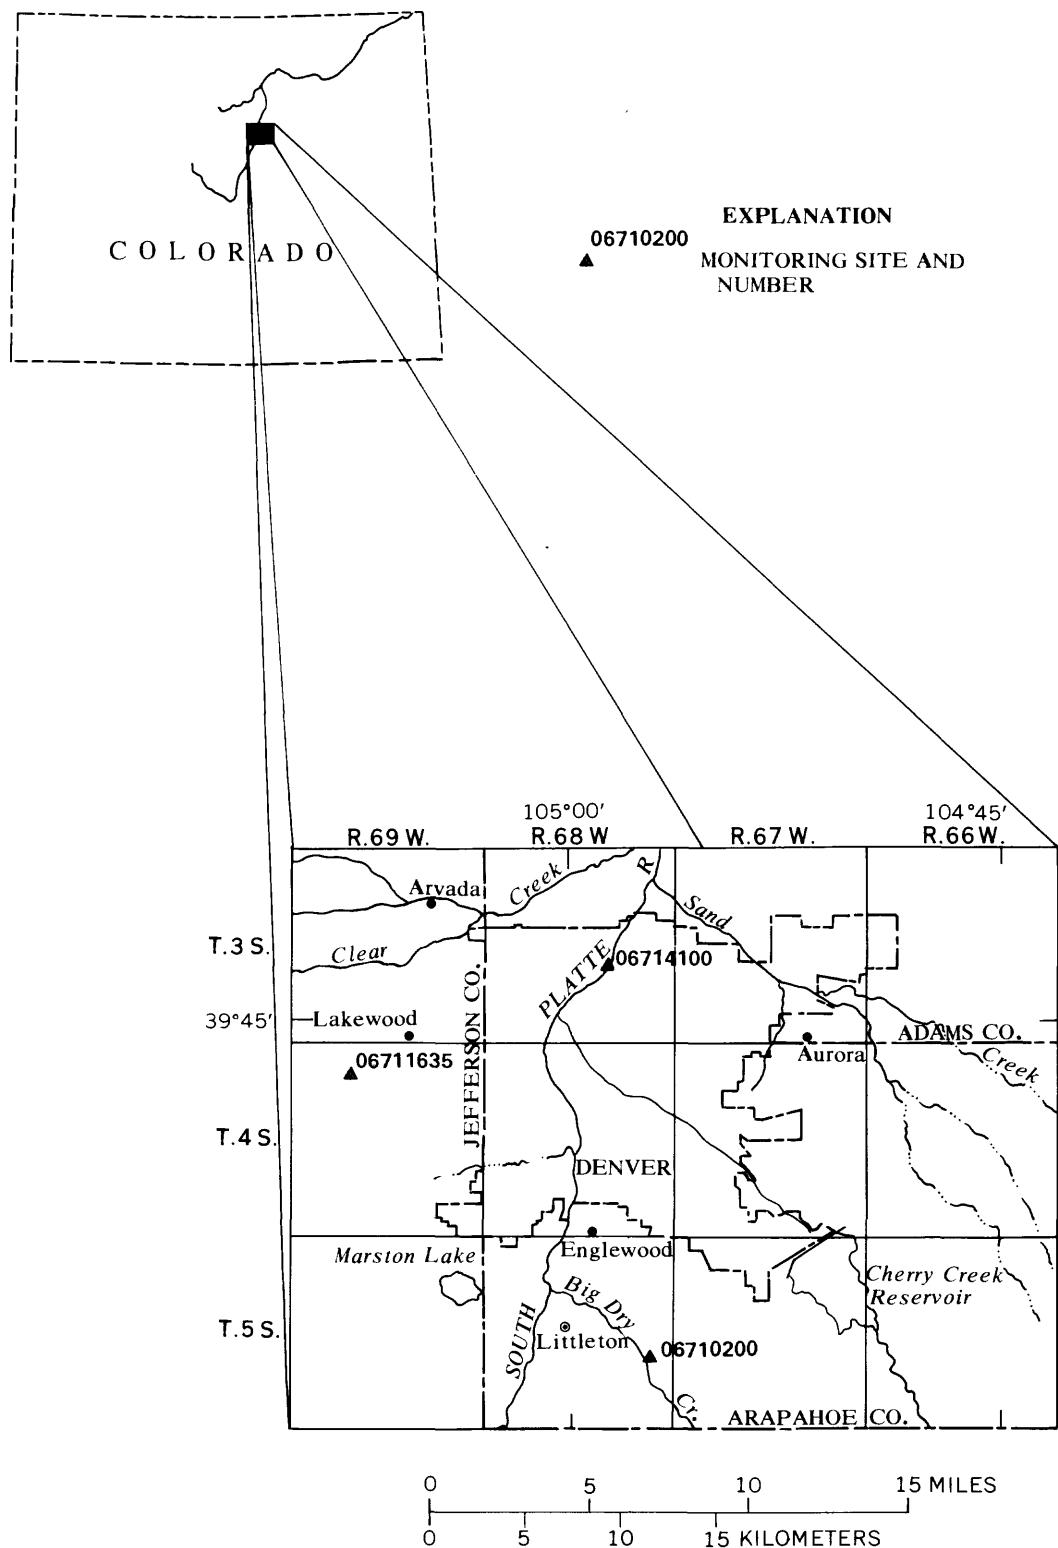

Figure 1.--Location of monitoring sites and general features.

Publication of the precipitation, hydraulic, and water-quality data is intended to serve two purposes:

1. To make the data available to planning, water-management, and environmental-protection agencies so that they may use the data to assist in assessing the impact of urban storm runoff on the hydrologic system.
2. To provide data needed to apply the U.S. Environmental Protection Agency's Storm Water Management Model II (Huber and others, 1975) or similar models to the catchment areas.

APPROACH

Automated water-quality sampling and rainfall-runoff monitors were installed at each site during February 1976. The automated monitor and its operation is described by Smoot, Davidian, and Billings (1974). Gage height-discharge relationships for sites 06711635 North Avenue Storm Drain at Denver Federal Center, at Lakewood, and 06714100 Thirty-sixth Street Storm Sewer at Denver, were derived using V-notch weirs and their theoretical ratings. The gage height-discharge relationship for site 06710200 Big Dry Creek tributary at Littleton was derived using the step-backwater approach (Shearman, 1976), supplemented by current-meter measurements.

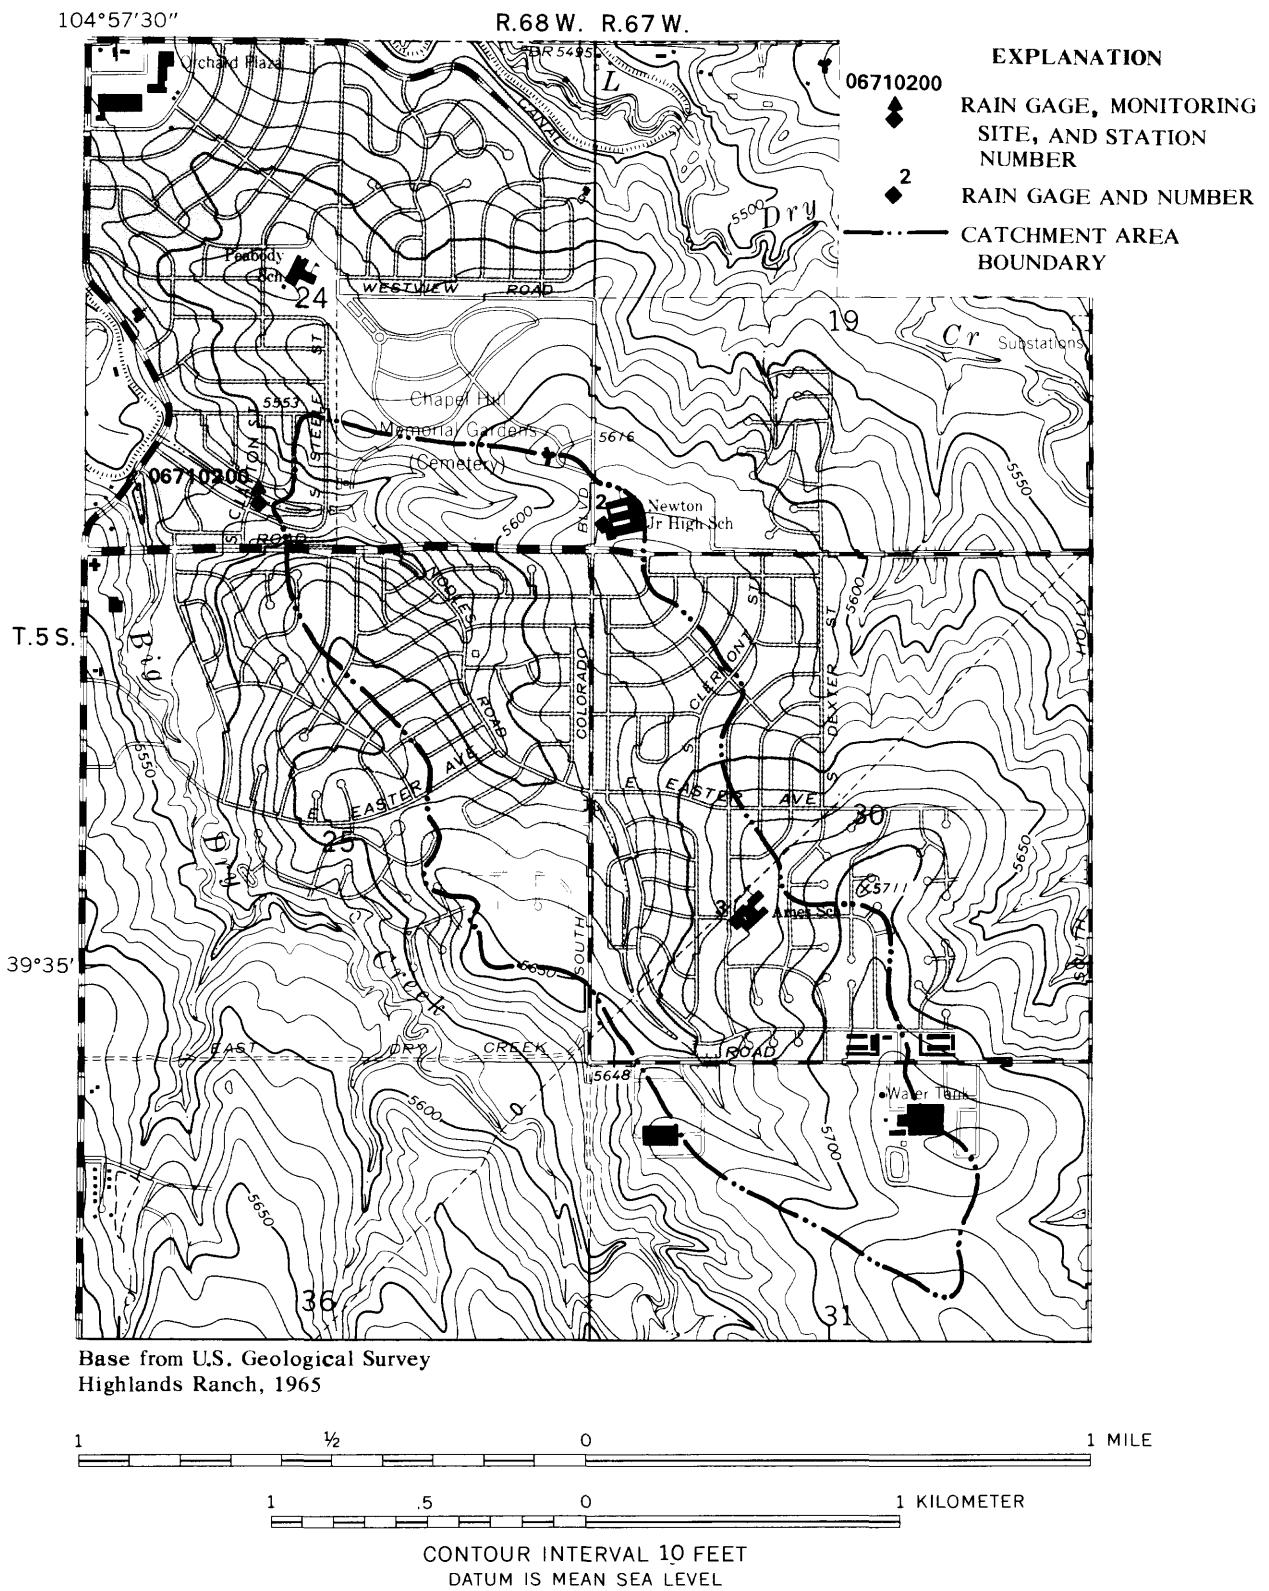

Prior to February 1976, samples for water-quality analysis were collected from the three sites at times that were not correlated with rainfall runoff. These samples, referred to as miscellaneous samples in this report, were analyzed for numerous water-quality constituents to determine which water-quality constituents were to be analyzed in samples collected later in the investigation, following installation of the monitors.

DESCRIPTION OF THE CATCHMENT AREAS

Littleton

The catchment area in Littleton (fig. 2) consists of 606 acres (0.95 square mile), of which approximately 75 percent is single-family dwellings and 25 percent is parks and open space. Approximately 15 percent of the catchment area is covered by effective impervious surfaces and 10 percent of the catchment area by noneffective impervious surfaces. The catchment area has essentially no storm-sewer system, relying mostly on street gutters and ditches for flow conveyance.

Three rain gages were installed in the catchment area (fig. 2). Rain gage 1 is located at the shelter housing the monitor, rain gage 2 is located at Newton Junior High School, and rain gage 3 is located at Ames Elementary School.

Base from U.S. Geological Survey
Highlands Ranch, 1965

Figure 2.--Outline of study area, and location of rain gages and monitoring site for the catchment area in Littleton drained by tributary to Big Dry Creek.

Lakewood

The catchment area in Lakewood (pl. 1) consists of 76.7 acres (0.12 square mile), of which approximately 50 percent is undeveloped land, about 30 percent is multifamily dwellings, and about 20 percent is commercial development. Approximately 30 percent of the catchment area is covered by effective impervious surfaces and approximately 10 percent by noneffective impervious surfaces. A trunk storm sewer crosses the catchment area in the center of the southern one-half of the area. Street gutters convey the runoff to the storm sewer.

One rain gage was installed in the catchment area at the shelter housing the monitor (pl. 1). The rain gage probably provides adequate rainfall data for the catchment area except during localized thunderstorms.

Denver

The catchment area in Denver (pl. 2) consists of 2,246 acres (3.5 square miles), of which about 37 percent is multifamily dwellings, about 37 percent is mixed single-family and multifamily dwellings, about 20 percent is commercial development, and 6 percent is parks. Some of the high-use commercial areas, especially near the South Platte River, contain several small industrial establishments. Approximately 40 percent of the catchment area is covered by effective impervious surfaces and about 25 percent of the catchment area by noneffective impervious surfaces. The catchment area is completely underlain by a complex storm-sewer system that conveys the runoff through the Thirty-sixth Street storm sewer. The catchment area is representative of other parts of the city's urban center.

Three rain gages were installed in the catchment area (pl. 2). Rain gage 1 is located at the shelter housing the monitor, rain gage 2 is located at Gilpin Elementary School, and rain gage 3 is located at Morey Junior High School.

RAINFALL DATA

Daily average rainfall data for the Littleton catchment area are presented in table 2, for the Lakewood catchment area in table 3, and for the Denver catchment area in table 4. The rainfall data for the Littleton catchment area (table 2) and the Denver catchment area (table 4) represent the average rainfall for each catchment area based on data collected from all the rain gages.

Rainfall data for the Denver catchment area are presented only for 1976 because periodic instrument malfunctions prevented obtaining a complete record for 1977. Rainfall data for Denver for 1977 may be obtained from the National Weather Service and can be used to obtain an estimate of daily rainfall for the Denver catchment area.

¹Gage discontinued October 7, 1976.

RAINFALL-RUNOFF DATA

Rainfall-runoff data obtained for the Littleton catchment area are presented in tables 5 through 13. Estimated values of runoff in the tables were determined using two different methods. All estimated values of runoff, except those for April 29, August 1, and September 7, 1976, were determined by manual plotting of a hydrograph and estimating the beginning and ends of the hydrograph. Estimated values of runoff for April 29, August 1, and September 7, 1976, were made using the Storm Water Management Model II (Huber and others, 1975). These estimates are subject to revision because of continuing calibration refinement of the model.

Additional rainfall-runoff data for the Littleton catchment area are presented in two reports by Ducret and Hodges (1972, 1975). The data presented in their reports may not correlate with the data presented in this report because in the previous reports rainfall was measured at one rain gage located at the present site of the monitor instead of the three rain gages used in this investigation. Also, the flow record was obtained from different measuring devices at about the same location. The above-stated differences need to be considered when computer modeling of the catchment area is attempted.

Rainfall-runoff data obtained for the Lakewood catchment area are presented in tables 14 through 22. Prior to March 1977, accurate measurements of runoff could not be obtained because of supercritical flow in the storm drain, even though several different methods for measuring runoff were used. In March 1977, a 90-degree V-notch weir was installed in the storm drain that allowed accurate measurements of runoff to be made. The rainfall-runoff data obtained after March 1977 were used to calibrate the Storm Water Management Model II (Huber and others, 1975), which was then used to estimate the runoff prior to March 1977. These estimates are subject to revision because of calibration refinement of the model.

1525	.30	.00	2100	.20	.00

Rainfall-runoff data obtained for the Denver catchment area are presented in tables 23 through 36. Prior to March 1977, accurate measurements of runoff between about 40 cubic feet per second and 100 cubic feet per second could not be obtained at times because of supercritical flow in the storm sewer. Estimated values of runoff for these periods were determined by comparison with similar runoff records without supercritical flow. These estimates are subject to revision because of possible calibration of the Storm Water Management Model II (Huber and others, 1975). In March 1977, an energy dissipator was installed "upstream" from the V-notch weir which reduced flow velocities through the weir to subcritical velocities enabling accurate measurements of runoff.

Table 23.--Rainfall-runoff data, April 29-30, 1976, for station 06714100 Thirty-sixth Street Storm Sewer at Denver

[Rainfall is reported in amounts measured during specified time increments; time increment is 5 minutes. e indicates estimated discharge]

WATER-QUALITY DATA

Miscellaneous Samples

Miscellaneous samples were collected manually for chemical analysis prior to February 1976, as described in the "Approach" section of this report. Results of the chemical analyses for the Littleton catchment area are presented in table 37, for the Lakewood catchment area in table 38, and for the Denver catchment area in table 39.

Samples of Runoff from Snowmelt and Rainfall

After installation of the automated water-quality sampling monitors in February 1976, samples of runoff for chemical analysis were collected for selected runoff periods. Sample collection usually started when runoff at the monitor sites began and continued until runoff ceased or approached base flow. Samples collected during March 1976 and from January through March 1977 are from snowmelt runoff; all other samples are from rainfall runoff.

Major Constituents

Samples were analyzed for the following major constituents and parameters: specific conductance, pH, hardness, noncarbonate hardness, alkalinity, sodium-adsorption ratio, silica, calcium, magnesium, sodium, potassium, manganese, bicarbonate, carbonate, sulfate, chloride, and fluoride.

Results of the analyses from the Littleton catchment area are presented in table 40, for the Lakewood catchment area in table 41, and for the Denver catchment area in table 42.

Nutrients, Biochemical Oxygen Demand, Coliform Bacteria, and Solids

Samples were analyzed for the following nutrients and related parameters: total nitrate, total nitrite, total nitrite plus nitrate, total ammonia, total organic nitrogen, total Kjeldahl nitrogen, total nitrogen, dissolved phosphorus, total orthophosphate, dissolved organic carbon, suspended organic carbon, biochemical oxygen demand 5-day, total- (immediate) coliform bacteria, fecal-coliform bacteria, fecal-streptococcus bacteria, dissolved solids, total nonfilterable residue, volatile nonfilterable residue, and suspended sediment. Biochemical oxygen demand data are probably affected by the presence of trace elements in the samples. Results of the analyses from the Littleton catchment area are presented in table 43, for the Lakewood catchment area in table 44, and for the Denver catchment area in table 45.

Trace Elements

Initially (May to November 1976), a rather complete suite of trace elements was analyzed. These comprehensive analyses were made to determine what trace elements were present in the runoff, what concentrations could be expected, and in what phase--particulate or dissolved--the trace elements occurred. Results of the analyses for the Littleton catchment area are presented in table 46 and for the Denver catchment area in table 47. Data are not available for the Lakewood catchment area.

The results of the comprehensive analyses indicated that most of the trace elements did not occur at concentrations large enough to warrant inclusion in subsequent analyses. Arsenic, copper, iron, lead, and zinc were detected at sufficient concentrations to warrant inclusion in subsequent analysis. The results also indicated that the particulate phase was considerably more prevalent than the dissolved phase. Thus, total phases of arsenic, copper, iron, lead, and zinc (particulate plus dissolved phases) were determined in subsequent samples.

Based on the results of the comprehensive analyses, samples collected after February 1977 were analyzed for total concentrations of arsenic, copper, iron, lead, and zinc. Results of the analyses for the Littleton catchment area are presented in table 48, for the Lakewood catchment area in table 49, and for the Denver catchment area in table 50.

Pesticides

Samples for analysis of pesticides were collected manually and analyzed in U.S. Geological Survey laboratories. Results of the analyses for the Littleton catchment area are presented in table 51, and for the Lakewood catchment area in table 52. Data are not available for the Denver catchment area.

DATA FOR USE WITH STORM WATER MANAGEMENT MODEL II

Data required to model various aspects of urban runoff in the three study areas using the U.S. Environmental Protection Agency's Storm Water Management Model II (Huber and others, 1975) were obtained from aerial photographs and topographic, drainage, and sewer-system maps. Data on subcatchment areas, street gutters, and sewer systems for the Littleton catchment area are presented in tables 53-54 and on figure 3, for the Lakewood catchment area in tables 55-56 and on figure 4, and for the Denver catchment area in tables 57-58 and on plate 3. Transport data for the Denver catchment area are presented in table 59. Transport data for the Littleton and Lakewood catchment areas are not required for the model.
